

# Extract Document Sources

## Description

Extracts a table containing one row per document source in the database. Typically document sources are journals, but they can also be books, conference proceedings, or other types of publications. See [Load ISI File Into Database/SOURCE](#) for more information.

## Analyses

In addition to the standard [Sources Table](#) fields in the database, 'Extract Document Sources' creates the aggregate column 'NUM\_PAPERS\_COUNTED\_FROM\_DATASET', which is the number of documents (usually papers) from the original dataset which are published in the document source.

## Usage Hints

This algorithm will only be as accurate as the journal disambiguation performed on the dataset. See [Merge Document Sources](#).

## Implementation Details

The specific query run by the tool can be found in the [source code](#).
